Neural Networks

Informal definition: simplified models of the brain

- large number of basic computing units: neurons
- connected in a complex network

Neuron

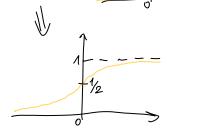

Neuron: function $\mathbf{x} \to \sigma(\langle \mathbf{v}, \mathbf{x} \rangle)$, with $\mathbf{x} \in \mathbb{R}^d$

 $\sigma: \mathbb{R}
ightarrow \mathbb{R}$ is the activation function

Example: \mathbb{R}^5 ner (moltiplicoverene) (x_1) x_2 v_2 v_3 $\sigma(\langle v, x \rangle)$ x_3 v_4 newore x_4 v_5

We will consider σ to be one among:

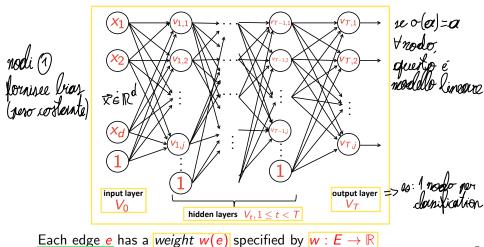

- sign function: $\sigma(a) = \text{sign}(a) = 7$
- threshold function: $\sigma(a) = \mathbb{1}[a > 0]$
- sigmoid function: $\sigma(a) = \frac{1}{1+e^{-a}}$

Neural Network (NN)

Obtained by connecting many neurons together.

We focus on **feedforward neural networks**, defined by a directed acyclic graph G = (V, E) organized in layers

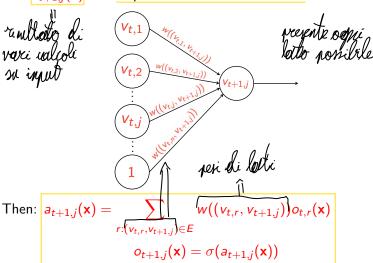

5

Point of View of One Node

Consider node $v_{t+1,j}$, $0 \le t < T$. Let

- $a_{t+1,j}(\mathbf{x})$: its <u>input</u> when \mathbf{x} is fed to the NN
- $o_{t+1,j}(\mathbf{x})$: its output when \mathbf{x} is fed to the NN

Neural Network: Formalism

Neural network: described by directed acyclic graph G = (V, E) and weight function $w : E \to \mathbb{R}$

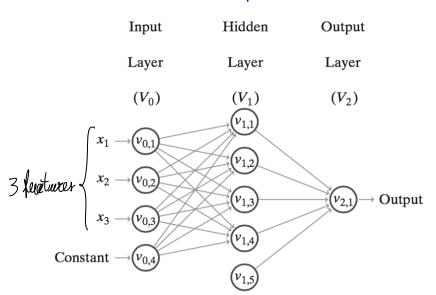

•
$$V = \bigcup_{t=0}^{T} V_t, V_i \cap V_j = \emptyset \ \forall i \neq j$$
 \Rightarrow partition in T+1 parti

- $e \in E$ can only go from V_t to V_{t+1} for some t
- $V_0 = input layer$
- $V_T = output layer$
- V_t , 0 < t < T = hidden layers
- T = depth
- |V| = size of the network
- $\max_{t} |V_t| = width$ of the network

Notes:

- for binary classification and regression (1 variable): output layer has 1 node
- different layers could have different activation functions (e.g., output layer)

Example

depth = 2, size = 10, width = 5

Exercize

Assume that for each node the activation function $\sigma(z): \mathbb{R} \to \mathbb{R}$ is defined as

$$\sigma(z) = \begin{cases} 1 & z \ge 1 \\ z & -1 \le z < 1 \\ -1 & z < -1 \end{cases}$$

and consider the neural network in the next slide, compute the value of the output y when the input $x \in \mathbb{R}^2$ is

$$\mathbf{x} = [1 \quad -3]^{\top}$$

Exercise (continue)

$$O(2) = \begin{cases} 1 & 2 \ge 1 \\ 2 & -1 \le 2 \le 1 \\ -1 & 2 \le 1 \end{cases}$$

$$x_1 + x_2 + x_3 = x_1 + x_2 + x_4 = x_3 = x_4 + x_5 = x_5 =$$

Hypothesis Set of a NN

Architecture of a NN: (V, E, σ)

Once we specify the architecture and w, we obtain a function:

$$h_{V,E,\sigma,w}: \mathbb{R}^{|V_0|-1} \to \mathbb{R}^{|V_T|}$$
input \Rightarrow realizatione

The *hypothesis class* of a neural network is defined by *fixing* its architecture:

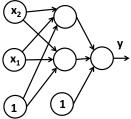

$$\mathcal{H}_{V,E,\sigma} = \{h_{V,E,\sigma,w} : w \text{ is a mapping from } E \text{ to } \mathbb{R}\}$$

Question: what type of functions can be implemented using a neural network?

Exercise (expressiveness of NNs)

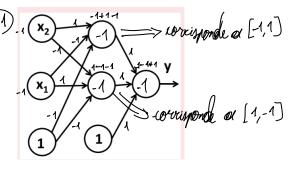

Let $\mathbf{x} = [x_1, x_2] \in \{-1, 1\}^2$, and let the training data be represented by the following table:

<i>x</i> ₁	<i>X</i> 2	y
-1	-1	-1
-1	1	1
1	-1	1
1	1	-1

Consider the NN in the figure above, where the activation function for each hidden node and the output node is the sign function. Assume that the network's weights are constrained to be in $\{-1,1\}$.

- 1 Find network's weights so that the training error is 0.
- 2 Use example above to motivate the fact that NNs are *richer* models than linear models.

2) Vraining set regpresenter XOR (non linearce) Non reppresentable son modelli linearci, ma si con NN GENERAL CONSTRUCTION luvriore auditrovia f: {-1,1}d > {-1,1} => > vogliano IIV ele "colloba" * (2) - prondiamo x (k(z)=1 → + x coxi, 3 neurone in unico hidden leujer she "cocci gonde" α > = implemente: $g_{\lambda}(\vec{x}') = \text{lign}(\langle \vec{x}, \hat{x} \rangle - d + 1)$ imput NN resi di bali resi di batto newcone y;(Z) ~covcisponde a

Expressiveness of NN

Proposition

For every d, there exists a graph (V, E) of depth 2 such that $\mathcal{H}_{V,E,\text{sign}}$ contains all functions from $\{-1,1\}^d$ to $\{-1,1\}$

11> tulli posoilili pesi

NN can implement every boolean function!

Unfortunately the graph (V, E) is very big...

Proposition

For every d, let s(d) be the minimal integer such that there exists a graph (V, E) with |V| = s(d) such that $\mathcal{H}_{V, E, \text{sign}}$ contains all functions from $\{-1, 1\}^d$ to $\{-1, 1\}$. Then s(d) is an exponential function of d.

Note: similar result for $\sigma = \text{sigmoid}$

Proposition

For every fixed $\varepsilon > 0$ and every Lipschitz function $f: [-1,1]^d \to [-1,1]$ it is possible to construct a neural network such that for every input $\mathbf{x} \in [-1,1]^d$ the output of the neural network is in $[f(\mathbf{x}) - \varepsilon, f(\mathbf{x}) + \varepsilon]$.

Note: first result proved by Cybenko (1989) for sigmoid activation function, requires only 1 hidden layer!

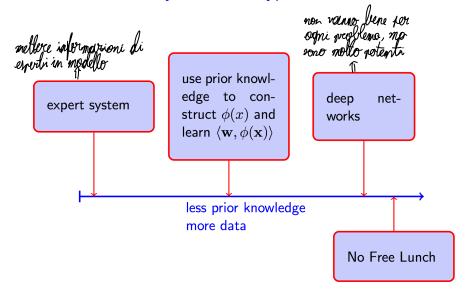

NNs are universal approximators! => jono pyvonimove note funcioni

But again...

Proposition

Fix some $\varepsilon \in (0,1)$. For every d, let s(d) be the minimal integer such that there exists a graph (V,E) with |V|=s(d) such that $\mathcal{H}_{V,E,\sigma}$, with $\sigma=$ sigmoid, can approximate, with precision ε , every 1-Lipschitz function $f:[-1,1]^d \to [-1,1]$. Then s(d) is exponential in d.

An Extremely Powerful Hypothesis Class...

Sample Complexity of NNs

How much data is needed to learn with NNs?

Proposition

The VC dimension of $\mathcal{H}_{V,E,\text{sign}} = O(|E| \log |E|)$

Different σ ?

Proposition

Let σ be the sigmoid function. The VC dimension of $\mathcal{H}_{V,E,\sigma}$ is:

- $\Omega(|E|^2)$
- $O(|V|^2|E|^2)$
- ⇒ large NNs require a lot of data!

100 000 NO

Question: assume we have a lot of data, can we find the best hypothesis?

Runtime of Learning NNs

Informally: applying the <u>ERM rule</u> with respect to $\mathcal{H}_{V,E,\text{sign}}$ is <u>computationally difficult</u>, even for small NN...

Proposition

Let $k \geq 3$. For every d, let (V, E) be a layered graph with d input nodes, k+1 nodes at the (only) hidden layer, where one of them is the constant neuron, and a single output node. Then, it is NP-hard to implement the ERM rule with respect to $\mathcal{H}_{V,E,\text{sign}}$.

Well maybe the above is only for very specific cases...

- instead of ERM rule, find h close to ERM? Computationally infeasible! (probably)
- other activation functions (e.g., sigmoid)? Computationally infeasible! (probably)
- smart embedding in larger network? Computationally infeasible! (probably)

So? $\underline{\textit{Heuristic}}$ for training NNs \Rightarrow $\underline{\textit{SGD}}$ algorithm and its improved versions are used: gives good results in practice!

Matrix Notation

neglio usare 690

Consider layer t, 0 < t < T:

- let $d^{(t)} + 1$ the number of nodes:
 - constant node 1
 - values of nodes for (hidden) variables: $v_{t,1}, \ldots, v_{t,d(t)}$
- arc from $v_{t-1,i}$ to $v_{t,j}$ has weight $w_{ij}^{(t)}$

Let

$$\mathbf{v}^{(t)} = \left(1, v_{t,1}, \dots, v_{t,d^{(t)}}
ight)^T$$

$$\mathbf{w}_j^{(t)} = \left(w_{0j}^{(t)}, w_{1j}^{(t)}, \dots, w_{d^{(t-1)}j}^{(t)}
ight)^T$$

$$v_{t,j} = \sigma\left(\langle \mathbf{w}_j^{(t)}, \mathbf{v}^{(t-1)} \rangle\right)$$

Note:

$$\mathbf{v}^{(t)} = \begin{bmatrix} 1 \\ v_{t,1} \\ \vdots \\ v_{t,d^{(t)}} \end{bmatrix} = \begin{bmatrix} 1 \\ \sigma\left(\langle \mathbf{w}_1^{(t)}, \mathbf{v}^{(t-1)}\rangle\right) \\ \vdots \\ \sigma\left(\langle \mathbf{w}_{d^{(t)}}^{(t)}, \mathbf{v}^{(t-1)}\rangle\right) \end{bmatrix}$$

Let

$$a_{t,j} := \langle \mathbf{w}_j^{(t)}, \mathbf{v}^{(t-1)}
angle$$

and

$$\mathbf{a}^{(t)} = \begin{bmatrix} a_{t,1} \\ \vdots \\ a_{t,d^{(t)}} \end{bmatrix} \qquad \qquad \sigma\left(\mathbf{a}^{(t)}\right) = \begin{bmatrix} \sigma\left(a_{t,1}\right) \\ \vdots \\ \sigma\left(a_{t,d^{(t)}}\right) \end{bmatrix}$$

$$\mathbf{v}^{(t)} = egin{bmatrix} 1 \ \sigma\left(\mathbf{a}^{(t)}
ight) \end{bmatrix}$$

Let

$$\mathbf{w}^{(t)} = \begin{bmatrix} w_{01}^{(t)} & w_{02}^{(t)} & \dots & w_{0d^{(t)}}^{(t)} \\ w_{11}^{(t)} & w_{12}^{(t)} & \dots & w_{1d^{(t)}}^{(t)} \\ \vdots & \vdots & \dots & \vdots \\ w_{d^{(t-1)}1}^{(t)} & w_{d^{(t-1)}2}^{(t)} & \dots & w_{d^{(t-1)}d^{(t)}}^{(t)} \end{bmatrix}$$

 $(\mathbf{w}^{(t)})$ describes the weights of edges from layer t-1 to layer t

$$\mathbf{a}^{(t)} = \left(\mathbf{w}^{(t)}
ight)^T \mathbf{v}^{(t-1)}$$

Using Matrix Notation Warm-Up: Forward Propagation Algorithm

Input: $\mathbf{x} = (x_1, \dots, x_d)^T$; NN with 1 output node **Output:** prediction y of NN;

Learning NN parameters

How do we compute the weights $w_{ij}^{(t)}$?

ERM: given training data $(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_m, y_m)$ pick $w_{ij}^{(t)}, \forall i, j, t$ (defining a specific model h) minimizing the training error:

$$L_{\mathcal{S}}(h) = \frac{1}{m} \sum_{i=1}^{m} \ell(h, (\mathbf{x}_i, y_i))$$

How?

Not easy!

Learning NN parameters (2),

pavalmitri resi

We use $\underline{\mathsf{GD}}$ seeing $\underline{\mathsf{L}_{S}(h)}$ as a function of $\underline{\mathsf{w}^{(t)}}, \forall 1 \leq t \leq T$:

GD Update rule:

$$\mathbf{w}^{(t)} \leftarrow \mathbf{w}^{(t)} - \eta \nabla L_{\mathcal{S}}(\mathbf{w}^{(t)})$$

where $\nabla L_S(\mathbf{w}^{(t)})$ is the gradient of L_S (and η is the learning parameter). To compute it we need $\forall t, 1 \leq t \leq T$:

$$\frac{\partial L_S}{\partial \mathbf{w}^{(t)}} = \frac{\partial}{\partial \mathbf{w}^{(t)}} \left(\frac{1}{m} \sum_{i=1}^m \ell(h, (\mathbf{x}_i, y_i)) \right) = \frac{1}{m} \sum_{i=1}^m \frac{\partial \ell(h, (\mathbf{x}_i, y_i))}{\partial \mathbf{w}^{(t)}}$$

$$\Rightarrow$$
 need $\frac{\partial \ell}{\partial \mathbf{w}^{(t)}}$

Learning NN parameters (3)

Definition: Sensitivity vector for layer t

$$\delta^{(t)} = \frac{\partial \ell}{\partial \mathbf{a}^{(t)}} = \begin{bmatrix} \frac{\partial \ell}{\partial a_{t,1}} \\ \vdots \\ \frac{\partial \ell}{\partial a_{t,d^{(t)}}} \end{bmatrix} = \begin{bmatrix} \delta_1^{(t)} \\ \vdots \\ \delta_{d^{(t)}}^{(t)} \end{bmatrix}$$

 $\delta^{(t)}$ quantifies how the training error changes with $\mathbf{a}^{(t)}$ (the inputs to the t layer - before the nonlinear transformation)

Learning NN parameters (4)

Consider a weight $w_{ii}^{(t)}$: a change in $w_{ii}^{(t)}$ changes only $a_{t,i}$ therefore by chain rule we have

$$\begin{split} \frac{\partial \ell}{\partial w_{ij}^{(t)}} &= \frac{\partial \ell}{\partial a_{t,j}} \cdot \frac{\partial a_{t,j}}{\partial w_{ij}^{(t)}} \\ &= \delta_j^{(t)} \cdot \frac{\partial}{\partial w_{ij}^{(t)}} \left(\sum_{k=0}^{d^{(t-1)}} w_{kj}^{(t)} v_{t-1,k} \right) \\ &= \delta_j^{(t)} \cdot v_{t-1,i} \\ & \text{Predictions for input} \end{split}$$

Therefore to compute the gradient we only need $\delta^{(t)} = \frac{\partial \ell}{\partial a^{(t)}} \ \forall t$. How can we compute it?

Learning NN parameters (5)

Since ℓ depends from $a_{t,j}$ only through $v_{t,j}$, then from chain rule:

$$\delta_{j}^{(t)} = \frac{\partial \ell}{\partial a_{t,j}}$$

$$= \frac{\partial \ell}{\partial v_{t,j}} \cdot \frac{\partial v_{t,j}}{\partial a_{t,j}}$$

$$= \frac{\partial \ell}{\partial v_{t,j}} \cdot \sigma'(a_{t,j})$$

(the last equality derives from the definition of $v_{t,i}$)

Learning NN parameters (6)

Consider $\frac{\partial \ell}{\partial v_{t,j}}$: we need to understand how loss ℓ changes due to changes in $v_{t,j}$

- change in $\mathbf{v}^{(t)}$ affects only $\mathbf{a}^{(t+1)}$ (and then ℓ)
- changes in $v_{t,j}$ can affect every $\frac{a_{t+1,k}}{a_{t+1,k}}$ (talli nodi in layer alono)
- ⇒ sum chain rule contributions

$$\begin{split} \frac{\partial \ell}{\partial v_{t,j}} &= \sum_{k=1}^{d^{(t+1)}} \frac{\partial a_{t+1,k}}{\partial v_{t,j}} \cdot \frac{\partial \mathbf{h} \ell}{\partial a_{t+1,k}} \\ &= \sum_{k=1}^{d^{(t+1)}} w_{jk}^{(t+1)} \cdot \delta_k^{(t+1)} \end{split}$$

Learning NN parameters (7)

Putting everything together:

$$\delta_j^{(t)} = \sigma'(a_{t,j}) \cdot \sum_{k=1}^{d^{(t+1)}} w_{jk}^{(t+1)} \delta_k^{(t+1)}$$

Notes:

- $\sigma'(a_{t,j})$ depends on the function σ chosen
- To compute $\delta_i^{(t)}$ need $\delta_k^{(t+1)}$, $1 \le k \le d^{(t+1)}$ $\Rightarrow backpropagation algorithm$
- To start: need $\delta^{(L)} = \frac{\partial \ell}{\partial \mathbf{a}^{(L)}}$ (sensitivity of final layer): depends on the loss ℓ used

Algorithm to compute sensitivities $\delta^{(t)}$, $\forall t$, for a given data point (\mathbf{x}_i, y_i) .

```
Input: data point (\mathbf{x}_i, y_i), NN (with weights w_{ij}^{(t)}, for 1 \leq t \leq T)

Output: \delta^{(t)} for t = 1, \ldots, T
compute \mathbf{a}^{(t)} and \mathbf{v}^{(t)} for t = 1, \ldots, T;
\delta^{(T)} \leftarrow \frac{\partial \ell}{\partial \mathbf{a}^{(T)}};
for t = T - 1 downto 1 do
\begin{bmatrix} \delta_j^{(t)} \leftarrow \sigma'(a_{t,j}) \cdot \sum_{k=1}^{d^{(\ell+1)}} w_{jk}^{(t+1)} \delta_k^{(t+1)} \text{ for all } j = 1, \ldots, d^{(t)};
return \delta^{(1)}, \ldots, \delta^{(T)};
```

Backpropagation Algorithm

This is the final backpropagation algorithm, based on SGD, to train a NN

```
Input: training data (x_1, y_1), \dots, (x_m, y_m), NN (no weights
Output: NN with weights w_{ii}^{(t)}
initialize w_{ii}^{(t)} for all i, j, t;
for s \leftarrow 0, 1, 2, \dots do /* until convergence
                                                                                */
    pick (\mathbf{x}_k, \mathbf{y}_k) at random from training data;
    /* forward propagation
                                                                                */
    compute v_{t,j} for all j, t from (\mathbf{x}_k, y_k);
    /* backward propagation
                                                                                */
    compute \delta_i^{(t)} for all j, t from (\mathbf{x}_k, y_k);
    w_{ii}^{(t)} \leftarrow w_{ii}^{(t)} - \eta v_{t-1,i} \delta_i^{(t)} for all i, j, t;
                                                                    /* update
      weights */
    if converged then return w_{ii}^{(t)} for all i, j, t;
```

Notes on Backpropagation Algorithm

- preprocessing: all inputs are normalized and centered
- initialization of $w_{ij}^{(t)}$?

 Random values around 0 regime where model is \approx linear

```
- w_{ij}^{(t)} \sim U(-0.7, 0.7) (uniform distribution)

- w_{ij}^{(t)} \sim N(0, \sigma^2) with small \sigma^2

- if all weights set to 0 \Rightarrow all neurons get the same weights
```

- when to stop?
 Usually combination of:
 - "small" (training) error;
 - "small" marginal improvement in error;
 - upper bound on number of iterations
- L_S(h) usually has multiple local minima
 ⇒ run stochastic gradient descent for different (random) initial weights

Regularized NN

Instead of training a NN by minimizing $L_S(h)$, find h that minimizes:

$$L_S(h) + \frac{\lambda}{2} \sum_{i,j,t} (w_{ij}^{(t)})^2$$

where $\lambda = regularization parameter$

How do we find h? SGD or improved algorithms.

Note: for layer t, gradient is $\nabla (L_S(h)) + \lambda \mathbf{w}^{(t)}$

This is called *squared weight decay regularizer*

Other regularizations are possible.
